

# Project Explanation Script

Day 7 of 7 — Your 2-Minute 'Walk Me Through This Project' Answer

## The Full Script (read aloud, ~2 minutes)

"I built an end-to-end analytics project for a fictional Indian online perfume retailer called AromaKart, using Excel, SQL, Python, and Tableau.

The business problem was that leadership didn't have a data-backed view of which brands, cities, or customers actually drove profitable revenue, whether their discounting was efficient, or why premium products seemed to get returned more often.

I started with an 18-month, 3,000-order dataset and validated it — checking for missing values, duplicates, and that the financial fields were internally consistent — before analyzing anything.

In Excel, I built a KPI dashboard driven entirely by formulas, so nothing was hardcoded. In SQL, I wrote queries answering 15 specific business questions, from monthly revenue trends to return rates by brand tier. In Python, I ran a deeper exploratory analysis and produced six charts. And in Tableau, I combined the key views into a single executive dashboard.

The headline findings were that revenue spikes 2-3x around Diwali and New Year, premium brands earn more per order but sell far less often than budget brands, premium products return at a meaningfully higher rate, and a small segment of repeat customers drives a disproportionate share of revenue.

From that, I recommended ramping inventory ahead of peak season, being more selective with premium discounting, and building a loyalty program targeted at top repeat customers."

## STAR-Format Breakdown (for behavioral follow-ups)

| Element   | Content                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| Situation | AromaKart had 18 months of order data but no analytics function to make sense of it.                                  |
| Task      | Build a data-backed view of revenue drivers, seasonality, and return-rate risk.                                       |
| Action    | Validated data, then analyzed it across Excel, SQL, Python, and Tableau, each answering different business questions. |
| Result    | 5 concrete recommendations: inventory timing, city/brand investment, discount strategy, and a loyalty-program build.  |

## If They Interrupt With 'Just Give Me the SQL Part'

"Sure — I wrote 15+ SQL queries in SQLite, from simple GROUP BY aggregations to CTEs computing repeat-customer revenue share. For example, I used a CTE to first calculate each customer's order count and total spend, then classified them as repeat vs. one-time and summed revenue by group — that showed repeat customers punch above their weight in revenue share."

## If They Ask 'What Was Hardest?'

"Making sure every number was internally consistent across four different tools. It's easy for a metric in Excel to quietly diverge from the same metric in Python if a filter or date boundary doesn't match exactly, so I cross-checked totals like overall revenue and order count across all four outputs before finalizing anything."

## Closing Line

"I'd love to bring that same habit — validate first, then let the business question drive the tool choice — to a real analytics team."
